Disease/Medical Condition

OSTEOPOROSIS
(also referred to as “thin” or “brittle” bones)

Date of Publication: March 11, 2013

Is the initiation of non-invasive dental hygiene procedures* contra-indicated?  No

- Is medical consult advised? No (assuming patient/client is already under medical care for osteoporosis and has no complicating oral features)

Is the initiation of invasive dental hygiene procedures contra-indicated?** No

- Is medical consult advised? No (assuming patient/client is already under medical care for osteoporosis and has no complicating oral features)
- Is medical clearance required? No
- Is antibiotic prophylaxis required? No
- Is postponing treatment advised? No

Oral management implications

- Low estrogen levels, which commonly occur in post-menopausal women, are associated with osteoporosis and decreased alveolar bone density. The risk of tooth loss is particularly high in osteoporotic women who smoke. Estrogen replacement therapy (ERT) may be beneficial in decreasing tooth loss in women with osteoporosis, as well as in reducing gingival inflammation and attachment loss.

- The majority of osteoporotic fractures result from low trauma (i.e., falls from standing height or lower). Fractures of the wrist are most common, followed by fractures of the upper arm. Wrist fractures tend to occur at a younger age than spine and hip fractures. Such fractures, especially in one’s dominant arm, may interfere with brushing and flossing ability.

- Patients/clients treated with injectable bisphosphonates (see below) should avoid invasive dental procedures if possible.

Oral manifestations

- Osteoporosis is associated with alveolar bone loss and an elevated risk of periodontal disease. Osteoporotic women, in particular, are at increased risk of alveolar bone resorption, attachment loss, tooth loss, and edentulosity.

- Bisphosphonate drugs (used to treat osteoporosis, in addition to Paget’s disease, multiple myeloma, and hypercalcemia of malignancy) can infrequently lead to osteonecrosis of the jaw (ONJ). Bisphosphonate-associated osteonecrosis (BON) can occur with the oral administration of bisphosphonates (which is typically the administration route for osteoporosis patients/clients, and includes risedronate and alendronate), but is rare. BON is a more common complication of injectable bisphosphonates (such as pamidronate and zoledronic acid), which are used in patients/clients with primary bone cancer or skeletal metastases. In the early stages of ONJ, no radiographic abnormalities can be seen and patients/clients are usually asymptomatic. However, patients/clients may develop severe pain due to necrotic bone becoming secondarily infected. A common initial complaint is the sudden presence of intraoral discomfort and roughness that may progress to involve the soft oral tissues surrounding the area of necrotic bone. Often progressive, BON may lead to areas of bony exposure and dehiscence, as well as extraoral fistula formation.

OSTEOPOROSIS
(also referred to as “thin” or “brittle” bones)

Related signs and symptoms

- Osteoporosis is a skeletal disorder characterized by low bone density and elevated risk of fracture. Spine, hip, and wrist fractures associated with osteoporosis are a significant cause of disability, mortality, health care utilization, and health care costs.
- Osteoporosis is more likely to develop if one does not reach optimal peak bone mass during one’s bone-building years.
- Persons at elevated risk for osteoporosis include those who are:
  - Female
  - Caucasian (white) or Asian
  - Post menopausal women
  - Older adults
  - Small in body size (thin)
  - Eating a diet low in calcium
  - Eating a diet low in Vitamin D or experiencing little sun exposure
  - Physically inactive
  - Drinking alcohol excessively
  - Taking certain medications (e.g., glucocorticoids, antiseizure drugs, and excessive thyroid hormone)

* Includes oral hygiene instruction, fitting a mouth guard, taking an impression, etc.

** Ontario Regulation 501/07 made under the Dental Hygiene Act, 1991. Invasive dental hygiene procedures are scaling teeth and root planing, including curetting surrounding tissue.
